## SENSITIVITY OF CHARACTERISTICS TO CHANGES IN RESISTANCES AND REACTANCES OF AN INDUCTION MOTOR Markov V.S.

## National Technical University "Kharkov Polytechnic Institute", Kharkov

The international standards set recommended limits on the variations of the parameters given by manufacturers. These limits are given as percentage tolerances, and their recommended values are generally not too difficult to achieve. IEC60034 part 1 describes the requirements for duty (as S1 to S9), ratings, operating conditions, temperature rise, tolerances and the like for rotating electrical machines. Regarding tolerances its section 9, Table VIII, gives values for the performance parameters such as losses, running power factor, slip, locked rotor current, locked rotor torque, breakdown torque, pull-up torque and moment of inertia. The standard does not set tolerances on the particular resistances and reactances of the equivalent circuit. In order to show how sensitive the torque-speed and stator current-speed curves are to changes in impedance values, Figure 1 was prepared for a typical 200 kW two-pole motor of the Design D type. The six components R<sub>1</sub>, X<sub>1</sub>, R<sub>2</sub>, X<sub>2</sub>, R<sub>c</sub> and X<sub>m</sub> were individually increased by 20% from their nominal values and the appropriate slip recalculated so that the nominal shaft output power was re-established. The following can be seen: changes in  $R_1$ ,  $R_c$  and  $X_m$  have little effect; changes in  $R_{20}$  and  $R_{21}$ increase the starting and run-up torque, but only change the current by a small amount; changes in  $X_1$ ,  $X_{20}$  and  $X_{21}$  reduce both the torque and the current.

The functions  $R_2(s)$  and  $X_2(s)$  can be approximated by the following simple

200kW 2-pole motor

Parameter sensitivity cases

 $\begin{array}{ll} R_2(s) \ = \ (R_{21} \ - \ R_{20})s \ + \\ R_{20} \ \mbox{ and } \ \ X_2(s) \ = \ (X_{21} \ - \ X_{20})s \ + \ X_{20}, \end{array}$ 

where the suffix  $_1$  refers to the standstill value, and suffix  $_0$  to the fullload value.

A 22 kW two-pole motor drives a water pump and is supplied from a 415 V, 50 Hz power system. Assume that there is no voltage dropped between the

supply and the motor. The full-load slip is 0,02208 per-unit. The following ohmic values apply at 415 V for an equivalent star-wound stator:  $R_1 = 0,179$ ,  $X_1 = 0,438$ ,  $R_{20} = 0,0145$ ,  $X_{20} = 0,823$ ,  $R_{21} = 0,253$ ,  $X_{21} = 0,333$ ,  $R_c = 115$ ,  $X_m = 17$ .
